Sol. 1(a)  Transfer of axial force at base of column

In order to provide a plain concrete block footing, full force transfer must be possible at the column base, without the need for reinforcement at the interface.

\[ P_u = 1.5 \times 330 \text{ kN} = 495 \text{ kN} \]

\[ P_{br,\text{max}} = 0.45 f_{ck} \frac{A_1}{\sqrt{A_2}} \]

\[ A_1 = A_2 = 300 \times 300 \text{ mm}^2 \]

\[ P_{br} = 0.45 \times 20 \times \sqrt{\frac{300^2}{300^2}} = 9 \text{ MPa} \]

\[ F_{br} = 9 \times 300^2 = 810 \text{ kN} > P_u = 495 \text{ kN} \]

Full transfer of force is possible without the need for reinforcement

Size of footing

Assuming the weight of footing and backfill to comprise 10% of axial load,

Base area required = \[ \frac{330 \times 1.1}{360} = 1.01 \text{ m}^2 \]

Provide 1 m \times 1 m footing
Thickness of footing

\[ D = \left( \frac{1000 - 300}{2} \right) \tan \alpha = 350 \tan \alpha \]

\[ \tan \alpha \geq 0.9 \sqrt{\frac{100q_{\text{max}}}{f_{\text{ck}}} + 1} \]

\[ \tan \alpha \geq 0.9 \sqrt{\frac{100 \times 360 \times 10^3}{10^6 \times 20} + 1} \]

\[ \tan \alpha \geq 1.51 \]

\[ D = 350 \times 1.51 = 528.5 \text{ mm} \approx 530 \text{ mm} \]

Hence provide a concrete block 1000 × 1000 × 530 mm

(ii) Minimum reinforcement to provide ‘tie action’ and to account for temperature and shrinkage effects.

\[ (A_{\text{st}})_{\text{min}} = \frac{0.12}{100} \times BD = \frac{0.12}{100} \times 1000 \times 530 = 636 \text{ mm}^2 \]

Provide 6-12 mm \( \phi \) bars \( (A_{\text{st}} = 678 \text{ mm}^2) \) both ways with a clear cover of 75 mm

Spacing < 5d or 300 mm Spacing = \[ \frac{1000 - 2 \times 75 - 2 \times \frac{12}{2}}{6 - 1} = 167.60 \text{ mm} \]

(iii) Check for gross base pressure
Assuming

$\gamma_{\text{concrete}} = 24 \text{ kN/m}^3$

$\gamma_{\text{soil}} = 18 \text{ kN/m}^3$

Actual gross soil pressure

$q_{\text{max}} = \frac{330}{1 \times 1} + 24 \times 0.53 + 18 \times 0.47$

$q_{\text{max}} = 330 + 12.7 + 8.5$

$q_{\text{max}} = 351.2 \text{ kN/m}^2$

$q_{a} = 360 \text{ kN/m}^2$ Hence, safe

If the specified safe bearing capacity is based on net soil pressure,

Actual net soil pressure

$q_{\text{net}} = \frac{330}{1 \times 1} + (24 - 18) \times 0.53$

$q_{\text{net}} = 333.2 \text{ kN/m}^2$

$q_{a} = 360 \text{ kN/m}^2$ hence safe

Sol. 3(c)

(i) Equilibrium of Torsion
It is torsion introduced as a result of maintaining equilibrium of structure. This type of torsion
occurs mainly in statically determinate structures. It is determined only by equation of equilibrium
and is independent of torsional or flexural stiffness of members.

e.g. A cantilever or a beam carrying an eccentric out of plane, transverse load or a beam curved in
plane under vertical load and a helical stair.

Compatibility Torsion:
It is the torsion induced in a member due to compatibility of rotations at the joint of interconnected
members.

e.g. A spandrel beam connected to a cross-beam, arch, slab or a shell; interconnected bridge
girders; horizontal grids.

As per IS 456 : 2000
Equivalent shear, 

\[ V_e = V_a + \frac{1.6 \times T_u}{b} \]

where \( V_a \) = shear, \( T_u \) = torsional moment, \( b \) = width of beam

and 

Equivalent moment, 

\[ M_e = M_a + T_u \left( \frac{1 + \frac{D}{b}}{1.7} \right) \]

(ii) Equilibrium torsion has to be transferred to supports by torsional resistance of members and cannot be ignored. It’s neglect will result in the vibration of equilibrium leading to disastrous collapse.

Consideration of compatibility type of torsion can be optional in design. Neglecting the torsional stiffness of spandrel beam, if it exists could only underestimate the actual strength of the structure. At the same time, it will lead to simplicity of analysis.

Torsional reinforcement is not calculated separately that required for bending and shear. Instead of that total longitudinal reinforcement is determined for a factitious bending moment which is a function of actual bending moment and torsion. Similarly web reinforcement is determined for a fictitious shear which is a function of actual shear and torsion.

(iii) In the reinforcement concrete beams to resist the torsion, two types of reinforcements are provided.

(a) **Longitudinal Reinforcement** :

Longitudinal reinforcement is provided to resist the equivalent bending moment \( M_e \), given by,

\[ M_e = M + M_t \]

where

\[ M_t = T_u \left( \frac{1 + \frac{D}{b}}{1.7} \right) \]

And if \( M_t > M_u \), we need to provide tensile reinforcement on the flexural compression side

\[ M_e - M_u = 0.87 f_y A_{st} (d - d') \]

(b) **Transverse Reinforcement** :

Transverse reinforcement is provided in the beams to resist the equivalent shear given by,

\[ V_e = V_a + 1.6 \frac{T_u}{b} \]

where \( T_u \) is the torsional moment

Analysis of end section :

Stress at top 

\[ \sigma_{\text{top}} = \frac{P}{A} - \frac{P \cdot z}{A} \]

Stress at bottom 

\[ \sigma_{\text{bottom}} = \frac{P}{A} + \frac{P \cdot z}{A} \]

\[ Z = \frac{b d^2}{6} = \frac{400 \times 600^2}{6} = 24 \times 10^6 \text{ mm}^3 \]

\[ \frac{P}{A} = \frac{1000 \times 10^3}{400 \times 600} = 4.16 \text{ N/mm}^2 \]
\[
\frac{P_e}{z} = \frac{1000 \times 10^3 \times 50}{24 \times 10^6} = 2.08 \text{ N/mm}^2
\]

Stress at top = \(4.16 - 2.08 = 2.08 \text{ N/mm}^2\)

Stress at bottom = \(4.16 + 2.08 = 6.24 \text{ N/mm}^2\)

Analysis of Mid Section:

External downward load = 160 kN

Upward point load provided by cable = \(2P \sin \theta\)

Since \(\theta\) is small,
\[
\sin \theta = \frac{50}{3000} = \frac{1}{60}
\]

Upward point load = \(2 \times 1000 \times \frac{1}{60} = 33.33 \text{ kN}\)

Net downward load = 160 - 33.33 kN = 126.67 kN

B.M. due to Net downwards load at mid-section = \(M\)

\[
M = \frac{P_{\text{net}}L}{4} = 126.67 \times \frac{6}{4} = 190 \text{ KN-m}

B.M due to dead load \(M_d\) = \(\frac{W^2}{8} = \frac{6 \times 6^2}{8} = 27 \text{ Knm}\) (\(W = 0.6 \times 0.4 \times 1 \times 25 = 6 \text{ kN/m}\))

Stress at top = \(\frac{P}{A} + \frac{P_e}{z} + \frac{M + M_d}{z}\)

Stress at bottom = \(\frac{P}{A} + \frac{P_e}{z} - \frac{M + M_d}{z}\)

\[
P
\frac{A}{z} = \frac{1000 \times 10^3}{400 \times 600} = 4.17 \text{ N/mm}^2
\]

\[
\frac{P_e}{z} = \frac{1000 \times 10^3 \times 50}{24 \times 10^6} = 2.08 \text{ N/mm}^2
\]

\[
\frac{M + M_d}{z} = \frac{(190 + 27) \times 10^6}{24 \times 10^6} = 9.04 \text{ N/mm}^2
\]

Stress at top = \(4.16 - 2.08 + 9.04\) = 11.12 MPa

Stress at bottom = \(4.16 + 2.08 - 9.04\) = -2.8 MPa

Let us take a thickness $= \frac{l_{eff}}{10} = 120 \text{ mm}$

For cantilever tread slab, thickness can be reduce at the free end upto 80 mm.

$\Rightarrow$ Average thickness $= \frac{120 + 80}{2} = 100 \text{ mm}$

Dead load $= 25 \times 0.1 \times 0.3 = 0.75 \text{ kN/m}$

Finishes $= 0.6 \times 0.3 = 0.18 \text{ kN/m}$

$\Rightarrow$ Factored D.L. $= 1.5 \times (0.75 + 0.18) = 1.40 \text{ kN/m}$

Live load: For residence L.L. $= 3 \text{ kN/m}^2$ or 1.3 kN at free end.

Case - 1: Factored imposed load $= 1.5 \times 3 \times 0.3 = 1.35 \text{ kN/m}$

Case - 2: Factored imposed load $= 1.5 \times 1.3 = 1.95 \text{ kN/m}$

B.M. due to dead load $= \frac{wT^2}{2} = \frac{1.40 \times 1.2^2}{2} = 1.01 \text{ kNm}$

B.M. due to imposed load $= \frac{1.35 \times T^2}{2} = 0.972 \text{ kNm}$

\[ A_{st}^+ > (A_u)^{\min} \]

Spacing of 10 mm dia bar
\[ = \frac{\pi \times 10^2 \times 1000}{325.43} = 253.08 \text{ mm} \]

Spacing \times 3d \times 150 = 450 \text{ mm}
\times 300 \text{ mm}
So provide 10 mm bar @ 250 mm c/c

Area of steel for max –ve BM (\( A_{st}^- \))

\[ M_u^- = 0.87 f_y A_{st} (d - 0.42x_u) \]
\[ 18.69 \times 10^6 = 0.87 \times 415 \times A_{st} (150 - 0.42x_u) \]
\[ x_u = \frac{0.36 f_{ck} b}{0.36 f_{ck} b} = \frac{0.87 \times 415 A_{st}}{0.36 \times 20 \times 1000} = 0.0501A_{st} \]
\[ 18.69 \times 10^6 = 0.87 \times 415 \times A_{st} (150 - 0.42 \times 0.0501 A_{st}) \]
\[ A_{st}^- = 363.66 \text{ mm}^2 \]
\[ A_{sl}^- > (A_{sl})_{\text{min}} \]

\[ \text{Spacing} = \frac{\pi \times 10^2}{363.66} \times 1000 = 215.97 \text{ mm} \]

Provide 10 mm dia bars @ 210 mm C/C

\[ \text{Area of distribution steel} = \frac{0.12BD}{100} = \frac{0.12 \times 1000 \times 175}{100} = 210 \text{ mm}^2 \]

\[ \text{Spacing of 8 mm bar} = \frac{\pi \times 8^2 \times 1000}{4} = 239.23 \text{ mm} \]

Provide 8 mm @ 230 mm C/C

\[ \text{Sol.8(a)} \]

Reaction at each support, \( R = 2.4 \times \frac{5}{2} = 6 \text{kN} \)

B.M. at quarter span, \( M_1 = R \times \frac{L}{4} - W \left( \frac{L}{4} \right)^2 \times \frac{1}{2} \)

\[ = 6 \times 1.25 - 2.4 \left( \frac{1.25}{2} \right)^2 \]

\[ = 5.625 \text{kN-m} \]

B.M. at mid-span\[ = \frac{Wl^2}{8} = \frac{2.4 \times 5^2}{8} = 7.50 \text{kN-m} \]

Shift of C-line from p-line, \( e' = \frac{M}{P} \)

\[ \text{Shift at quarter span, } e'_1 = \frac{5.625 \times 10^3}{75} \]

\[ = 75 \text{ mm} \]
Eccentricity of C-line = \(-50 + 75 = 25\) mm above centroidal axis

Shift at mid-span, \(e'' = \frac{7.5 \times 10^3}{75} = 100\) mm

Eccentricity of C-line = \(100 - 50 = 50\) mm above centroidal axis

\[
\text{Stress at top at Mid-span} = \frac{P}{A} + \frac{P_e}{z}
\]
\[
\text{Stress at bottom at mid-span} = \frac{P}{A} - \frac{P_e}{z}
\]
\[
P = \frac{75 \times 10^3}{100 \times (300)} = 2.5 \text{ N/mm}^2
\]
\[
P_e = \frac{75 \times 10^3 \times 50}{100 \times (300)^2 / 6} = 2.5 \text{ N/mm}^2
\]
\[
\sigma_{\text{top}} = 2.5 + 2.5 = 5 \text{ N/mm}^2
\]
\[
\sigma_{\text{bottom}} = 2.5 - 2.5 = 0 \text{ N/mm}^2
\]

\text{Sol. 8(b)}

\[
D_t = 100 \text{ mm}
\]
\[
b_w = 250 \text{ mm}

\[
f_{ck} = 20 \text{ MPa}

\text{Case I : Assuming}

\[
x_u < D_t
\]
\[
C = T
\]
\[
0.36f_{ck}b_t x_u = 0.87 f_y A_{st}
\]
Conventional Class Test-1 (RCC) 4th March 2019

\[
x_u = \frac{0.87f_{y_{st}}A_{st}}{0.36f_{ck}b_f} = \frac{0.87 \times 250 \times 3694.51}{0.36 \times 20 \times 850} = 131.30 \text{ mm}
\]

\[\Rightarrow\] Assumption is not correct as \(x_u > 100 \text{ mm}\)

**Case II:** Assuming \(x > \frac{7}{3}D_f\)

\[
C = T
0.36f_{ck}b_wx_u + 0.45f_{ck}(B_f - b_w)D_f = 0.87f_{y_{st}}A_{st}
0.36 \times 20 \times 250 \times x_u + 0.45 \times 20(850 - 250) \times 100 = 0.87 \times 250 \times 3694.51
x_u = 146.42 \text{ mm}
\frac{7}{3}D_f = 233.33 \text{ mm}
D_f = 100 \text{ mm}
\]

\[\Rightarrow\] Assumption is not correct.

**Case III:**

\(D_f < x < \frac{7}{3}D_f\)

\[
C = T
0.36f_{ck}b_wx_u + (b_f - b_w)y_f \times 0.45f_{ck} = 0.87f_{y_{st}}A_{st}
y_f = 0.15x_u + 0.65D_f
\]
0.36 × 20 × 250 × x_u + (850 − 250) × (0.15x_u + 0.65 × 100) × 0.45 × 20
= 0.87 × 250 × 3694.51
x_u = 173.39 mm

y_f = 0.15 × 173.39 + 0.65 × 100
= 90.01 mm

M_u = 0.36f_{ck}b_w(d − 0.42x_u) + 0.45f_{ck}(B_f − b_w)y_f\left(\frac{d − y_f}{2}\right)
= 0.36 × 20 × 250 × 173.23(520 − 0.42 × 173.23)
+ 0.45 × 20 × (850 − 250) × 90.01 × \left(\frac{520 − 90.01}{2}\right)
= 370.33 kN-m

Sol. 8(c) Under-Reinforced and Over-Reinforced Section

(i) Under Reinforced Section: An under reinforced section is the one in which the percentage of steel provided is less than critical one and therefore full strength of concrete in compression is not developed. The actual neutral axis of such a section will fall above the critical neutral axis of a balanced section.

Figure below shows the under-reinforced section in which the actual N.A. is above the critical N.A. Let \(c\) be the permissible stress in concrete and \(t\) be the permissible stress in steel. If full permissible compressive stress \(c\) is permitted to be developed in concrete, the corresponding stress \(t_1\) in steel will be such that \(t_1/m\). Evidently, since \(t_1 > t\), full compressive stress \(c\) cannot develop in concrete. Instead, a compressive stress \(c_1\) is developed of such a magnitude that \(t_1/m = \sigma_{st}\) is obtained. Thus, in a under-reinforced concrete, the concrete is not fully stressed to its permissible value when stress in steel reaches its maximum value of \(t = \sigma_{st}\). The moment of resistance of an under-reinforced section is, therefore, computed on the basis of the tensile force in steel:

\[ M_r = tA_{st} \cdot jd = \sigma_{st} \times A_{st} \cdot jd \]

(ii) Over-Reinforced Section: In an over-reinforced section, the reinforcement provided is more than critical one and therefore the actual N.A. of such a section falls below the critical N.A. of a balanced section.

Figure shows an over-reinforced section in which the actual N.A. falls below the critical one. If stress in steel is permitted to be equal to maximum permissible value \(t\) the corresponding stress in concrete will be equal to \(c_1\), which is greater than permissible value \(c\) in concrete. Hence the stress distribution will be governed by line DOE (and not \(D_1\ O\ E_1\)), giving rise to a stress \(t_1\) in steel which is lesser than \(t\). Thus, in an over-reinforced section, steel reinforcement is not fully stressed to its permissible value.
and the moment of resistance is determined on the basis of compressive force developed in concrete:

\[ M = \frac{1}{2} c . k . d . b . j . d = \frac{1}{2} c . j . k . b . d^2 = \frac{1}{2} \sigma_{cbc} \cdot j . k . b . d^2 \]

or

\[ M = \frac{1}{2} c . n . \left( d - \frac{n}{3} \right) b = \frac{1}{2} \sigma_{cbc} \cdot n \left( d - \frac{n}{3} \right) b \]

Sol. 8. (d)

\[
A_{at} = \frac{4 \times \pi}{4} \times (20)^2 = 1256.6 \text{ mm}^2
\]

Adopting a min eccentricity of 20 mm

0.05 \(D\) = 0.05 \(450\) = 22.5 mm

\(e_{min}\) < 0.05 \(D\) hence ultimate load is given by

\[
P_u = 0.4 f_{ca} A_c + 0.67 f_y A_s
\]

\[
P_u = 0.4 \times 20 \times (450 \times 450 - 1256.6) + 0.67 \times 415 \times 1256.6
